Functions for portfolio selection

```
Enrico Schumann
es@enricoschumann.net
https://CRAN.R-project.org/package=NMOF
```

A main topic of Gilli et al. [2019] is non-standard portfolio-selection models; see Chapters 12–14. Nevertheless, the NMOF package also offers several functions that help with standard portfolio models, i.e. models that can be solved with traditional optimisation techniques such as quadratic programming.

1 Minimum-variance portfolios

The function minvar computes the minimum-variance portfolio for a given variance—covariance matrix, minvar subject to holding-size constraints. As example data, the variable var contains a small variance—covariance matrix, computed from daily returns of five German stocks. The data are taken from http://enricoschumann.net/data/gilli_accuracy.html; the code to build the matrix is in the source file of this vignette.

```
CBK.DE VOW.DE CON.DE LIN.DE MUV2.DE

CBK.DE 0.000988 -1.80e-05 3.69e-04 2.08e-04 2.63e-04

VOW.DE -0.000018 1.72e-03 8.57e-05 2.15e-05 2.84e-05

CON.DE 0.000369 8.57e-05 7.59e-04 1.94e-04 1.89e-04

LIN.DE 0.000208 2.15e-05 1.94e-04 2.66e-04 1.33e-04

MUV2.DE 0.000263 2.84e-05 1.89e-04 1.33e-04 2.59e-04
```

An example call, with minimum and maximum holding sizes specified.

```
> minvar(var, wmin = 0, wmax = 0.5)

[1] 6.94e-18 9.25e-02 4.69e-05 4.45e-01 4.62e-01
attr(,"variance")
[1] 0.000182
```

The function returns the portfolio weights with an attribute variance that provides the variance of this portfolio. The holding size constraints can also be specified as vectors, with different values for different assets.

Use Inf to switch off weight constraints.

```
> minvar(var, wmin = -Inf, wmax = Inf) ## no bounds
> minvar(var, wmin = -Inf, wmax = 0.45) ## no lower bounds
> minvar(var, wmin = 0.1, wmax = Inf) ## no upper bounds
```

The function also supports group constraints:

```
> ## group 1 consists of asset 1 only, and must have weight [0.25,0.30] > ## group 2 consists of assets 4 and 5, and must have weight [0.10,0.20] > minvar(var, wmin = 0, wmax = 0.40, groups = list(1, 4:5), groups.wmin = c(0.25, 0.1), groups.wmax = c(0.30, 0.2))
```

```
[1] 0.250 0.217 0.333 0.149 0.051 attr(,"variance")
[1] 0.000357
```

Alternatively, group constraints can be specified through group names instead of positions.

2 Mean-variance efficient portfolios and frontiers

The function mvPortfolio computes a mean-variance-efficient portfolio for a given variance-covariance mvPortfolio matrix and mean-return assumption, subject to holding-size constraints. We make up some data for four assets, with a constant correlation of 0.5.

One way to compute a mean-variance-efficient portfolio is by requiring a minimum return.

```
> mvPortfolio(m, var, min.return = 0.08, wmax = 1)
[1] 0.667 0.333 0.000 0.000
> mvPortfolio(m, var, min.return = 0.10, wmax = 1)
[1] 3.33e-01 6.67e-01 0.00e+00 3.10e-18
> mvPortfolio(m, var, min.return = 0.12, wmax = 1)
[1] -1.11e-16 1.00e+00 -5.55e-17 2.64e-17
```

Alternatively, we may specify a trade-off between return and variance and minimise

$$-\lambda m'w + \frac{1}{2}(1-\lambda)w'$$
var w ,

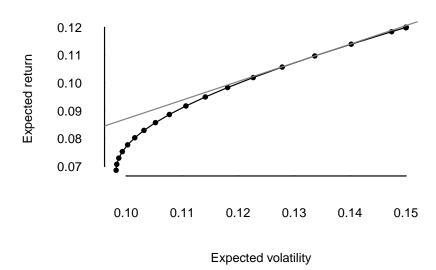

in which w are the weights. If λ is a vector of length 2, then the function minimises

$$-\lambda_1 \mathbf{m}' w + \frac{1}{2} \lambda_2 w' \mathbf{var} w.$$

The function mvFrontier traces out a whole frontier of mean-variance efficient portfolios. (But see the mvFrontier discussion on frontiers in Chapter 14 of Gilli et al., 2019.)

```
> if (requireNamespace("quadprog")) {
    wmin <- 0
    wmax <- 1
    p1 <- mvFrontier(m, var, wmin = wmin, wmax = wmax, n = 50)

## with a 'risk-free' asset rf</pre>
```

3 Return-based tracking portfolios

Function trackingPortfolio computes a portfolio that is close to another portfolio in the mean-square/ trackingPortfolio variance sense. The function to be minimised is determined by argument objective: supported are variance (the default) or sum.of.squares.

4 Minimum-Expected-Shortfall portfolios

Function minCVaR computes a portfolio that minimises conditional Value-at-Risk; its default method is minCVaR

the LP approach described in Rockafellar and Uryasev [2000]. See *Minimising Conditional Value-at-Risk* (CVaR) (http://enricoschumann.net/notes/minimising-conditional-var.html) for more details

```
> ns <- 5000 ## number of scenarios
> na <- 20 ## number of assets
> R <- randomReturns(na, ns, sd = 0.01, rho = 0.5)
> if (requireNamespace("Rglpk")) { ## example requires "Rglpk" package sol <- minCVaR(R, q = 0.1)
} else
    message("Package ", sQuote("Rglpk"), " not available")</pre>
```

5 Minimum Mean–Absolute-Deviation portfolios

Function minMAD computes a portfolio that minimises the mean absolute-deviation of portfolio returns, as minMAD described in Konno and Yamazaki [1991].

```
> ns <- 5000 ## number of scenarios
> na <- 5 ## number of assets
> R <- randomReturns(na, ns, sd = 0.01, rho = 0.5)
> minMAD(R = R)
[1] 0.197 0.176 0.185 0.256 0.187
```
