Package 'PanelMatch'

December 13, 2025

Type Package Title Matching Methods for Causal Inference with Time-Series Cross-Sectional Data Version 3.1.3 Date 2025-12-12 **Description** Implements a set of methodological tools that enable researchers to apply matching methods to time-series cross-sectional data. Imai, Kim, and Wang (2023) http://web.mit.edu/insong/www/pdf/tscs.pdf proposes a nonparametric generalization of the difference-in-differences estimator, which does not rely on the linearity assumption as often done in practice. Researchers first select a method of matching each treated observation for a given unit in a particular time period with control observations from other units in the same time period that have a similar treatment and covariate history. These methods include standard matching methods based on propensity score and Mahalanobis distance, as well as weighting methods. Once matching and refinement is done, treatment effects can be estimated with standard errors. The package also offers diagnostics for researchers to assess the quality of their results. **License** GPL (>= 3) **Imports** Rcpp (>= 0.12.5), data.table, ggplot2, CBPS, stats, graphics, MASS, Matrix, doParallel, foreach, methods **Depends** R (>= 2.14.0) LinkingTo RcppArmadillo, Rcpp, RcppEigen **Encoding UTF-8** LazyData true BugReports https://github.com/insongkim/PanelMatch/issues RoxygenNote 7.3.1

 $confint. Panel Estimate \ \textit{Produce confidence intervals for Panel Estimate objects}$

Description

Produce confidence intervals for PanelEstimate objects

Usage

```
## S3 method for class 'PanelEstimate'
confint(object, parm = NULL, level = NULL, ..., bias.corrected = FALSE)
```

Arguments

object	PanelEstimate results
parm	Not used.
level	Confidence level to be used for confidence interval calculations. Must be numeric between 0 and 1. If NULL, confidence level from PanelEstimate() specification is used.
	not used
bias.corrected	logical indicating whether or not bias corrected estimates should be provided. Default is FALSE. This argument only applies for standard errors calculated with the bootstrap.

Value

Matrix with two columns and 'length(lead)' rows. Contains the upper and lower boundaries of the confidence interval for each time period's point estimate.

4 DisplayTreatment

dem

Country-year level democratization data

Description

A dataset containing the democracy indicator for 184 countries from 1960 to 2010

Format

A data.frame containing 9384 rows and 3 variables

Details

- wbcode2. World Bank country ID. Integer.
- year. year (1960–2010). Integer.
- dem. binary indicator of democracy as defined in Acemoglu et al (2019).
- y log of GDP per capita in 2000 constant dollars (multiplied by 100). Numeric.
- tradewb Exports plus imports as a share of GDP from World Bank. Numeric.

DisplayTreatment Visualize the treatment distribution across units and time in a panel data set

Description

Visualize the treatment distribution across units and time in a panel data set

```
DisplayTreatment(
  panel.data,
  color.of.treated = "red",
  color.of.untreated = "blue",
  title = "Treatment Distribution \n Across Units and Time",
  xlab = "Time",
  ylab = "Unit",
  x.size = NULL,
  y.size = NULL,
  legend.position = "none",
```

DisplayTreatment 5

```
x.angle = NULL,
y.angle = NULL,
legend.labels = c("not treated", "treated"),
decreasing = FALSE,
matched.set = NULL,
show.set.only = FALSE,
hide.x.tick.label = FALSE,
hide.y.tick.label = FALSE,
gradient.weights = FALSE,
dense.plot = FALSE
```

Arguments

panel.data PanelData object

color.of.treated

Color of the treated observations provided as a character string (this includes hex values). Default is red.

color.of.untreated

Color of the untreated observations provided as a character string (this includes

hex values). Default is blue.

title Title of the plot provided as character string

xlab Character label of the x-axis ylab Character label of the y-axis

x.size Numeric size of the text for xlab or x axis tick labels. Assign x.size = NULL to

use built in ggplot2 method of determining label size. When the length of the time period is long, consider setting to NULL and adjusting size and ratio of the

plot.

y.size Numeric size of the text for ylab or y axis tick labels. Assign y.size = NULL to

use built in ggplot2 method of determining label size. When the number of units is large, consider setting to NULL and adjusting size and ratio of the plot.

legend.position

Position of the legend. Provide this according to ggplot2 standards.

x.angle Angle (in degrees) of the tick labels for x-axisy.angle Angle (in degrees) of the tick labels for y-axis

legend.labels Character vector of length two describing the labels of the legend to be shown

in the plot. ggplot2 standards are used.

decreasing Logical. Determines if display order should be increasing or decreasing by the

amount of treatment received. Default is decreasing = FALSE.

matched.set (optional) a matched.set object containing a single treated unit and a set of

matched controls. If provided, this set will be highlighted on the resulting plot.

show.set.only (optional) logical. If TRUE, only the treated unit and control units contained in

the provided matched. set object will be shown on the plot. Default is FALSE.

If no matched. set is provided, then this argument will have no effect.

6 distances

```
hide.x.tick.label
```

logical. If TRUE, x axis tick labels are not shown. Default is FALSE.

hide.y.tick.label

logical. If TRUE, y axis tick labels are not shown. Default is FALSE.

gradient.weights

(optional) logical. If TRUE, the "darkness"/shade of units in the provided matched.set object will be displayed according to their weight. Control units with higher weights will appear darker on the resulting plot. Control units with lower weights will appear lighter. This argument has no effect unless a matched.set is provided.

dense.plot

logical. if TRUE, lines between tiles are removed on resulting plot. This is useful for producing more readable plots in situations where the number of units and/or time periods is very high.

Value

DisplayTreatment returns a treatment variation plot (generated via ggplot2 geom_tile() or geom_raster()), which visualizes the variation of treatment across units and time. The results can be customized using ggplot2 syntax.

Examples

distances

Get distances See distances.matched.set method

Description

Get distances See distances.matched.set method

```
distances(object)
```

distances.matched.set 7

Arguments

object matched.set object

distances.matched.set Extract the distances of matched control units

Description

Extract the distances of matched control units

Usage

```
## S3 method for class 'matched.set'
distances(object)
```

Arguments

object

a matched.set object

Value

A named list of named vectors. Each element corresponds to a matched set and will be a named vector, where the names of each element will identify a matched control unit and its distance from the treated observation within a particular matched set. These correspond to the "distances" attribute, which are calculated and included when the verbose option is set to TRUE in PanelMatch.

8 estimates.PanelEstimate

estimates Extract QOI estimates See documentation for 'estimates. Panel Estimate()'

Description

Extract QOI estimates See documentation for 'estimates.PanelEstimate()'

Usage

```
estimates(object, ...)
```

Arguments

object PanelEstimate object
... other arguments. Not used.

estimates.PanelEstimate

Extract QOI estimates

Description

This is a method for extracting point estimates for the QOI from PanelEstimate objects. This function is analogous to the 'coef()' method used elsewhere.

Usage

```
## S3 method for class 'PanelEstimate'
estimates(object, ...)
```

Arguments

object PanelEstimate object
... not used

Value

Named vector with the QOI point estimates and the time periods to which they correspond

extract 9

extract

Extract matched.set objects from PanelMatch results

Description

Extract matched.set objects from PanelMatch results

Usage

```
extract(pm.object, qoi)
```

Arguments

pm.object PanelMatch object

qoi character, specifying the qoi. Valid inputs include "att", "atc", "art", and NULL.

If NULL, function extracts att, art, or atc results if possible. Otherwise, throws

an error if ate is specified.

extract.PanelMatch

Extract matched.set objects from PanelMatch results

Description

Extract matched.set objects from PanelMatch results

Usage

```
## S3 method for class 'PanelMatch'
extract(pm.object, qoi = NULL)
```

Arguments

pm.object PanelMatch obect

qoi character, specifying the qoi. Valid inputs include "att", "atc", "art", and NULL.

If NULL, function extracts att, art, or atc results if possible. Otherwise, throws

an error if ate is specified.

Value

```
a matched.set object
```

Examples

formula.PanelMatch

Return the refinement formula used in a PanelMatch specification

Description

Return the refinement formula used in a PanelMatch specification

Usage

```
## S3 method for class 'PanelMatch' formula(x, \ldots)
```

Arguments

x A PanelMatch Object not used

Value

One sided formula object containing the variables/specification used in refinement. This corresponds to what was provided to the covs.formula argument.

Description

Calculate covariate balance for user specified covariates across matched sets. Balance is assessed by taking the average of the difference between the values of the specified covariates for the treated unit(s) and the weighted average of the control units across all matched sets. Results are standardized and are expressed in standard deviations. Balance is calculated for each period in the specified lag window.

get_covariate_balance 11

Usage

```
get_covariate_balance(..., panel.data, covariates, include.unrefined = TRUE)
```

Arguments

... one or more PanelMatch objects

panel.data PanelData object

covariates a character vector, specifying the names of the covariates for which the user is

interested in calculating balance.

include.unrefined

logical. Indicates whether or not covariate balance measures for unrefined matched sets should be included. If TRUE, the function will return covariate balance results for the PanelMatch configurations provided, as well as a set of balance results that assume all matched controls have equal weight (i.e., the matched sets are unrefined). These results are included in addition to whatever PanelMatch configurations are specified to the function. Note that if you provide a Panel-Match object where no refinement is applied (that is, where refinement.method = "none") and set this option to TRUE, then both sets of covariate balance results will be identical. If FALSE, then only balance calculations for the provided PanelMatch specifications are performed and returned.

Value

A list of matrices, or a list of lists (if the QOI is ATE). The matrices contain the calculated covariate balance levels for each specified covariate for each period. Each element in the list (whether that be a matrix or a sublist) corresponds to a PanelMatch configuration specified to the function. Results are returned in the order they were provided. Unrefined results are stored as a parallel list object in an attribute called "unrefined.balance.results".

```
get_set_treatment_effects
```

Calculate matched set level treatment effects

Description

Calculate the size of treatment effects for each matched set.

Usage

```
get_set_treatment_effects(pm.obj, panel.data, lead)
```

Arguments

pm.obj an object of class PanelMatch

panel.data PanelData object with the time series cross sectional data used for matching,

refinement, and estimation

lead integer (or integer vector) indicating the time period(s) in the future for which

the treatment effect size will be calculated. Calculations will be made for the period t + lead, where t is the time of treatment. If more than one lead value is

provided, then calculations will be performed for each value.

Value

a list equal in length to the number of lead periods specified to the lead argument. Each element in the list is a vector of the matched set level effect estimates.

get_unrefined_balance 13

get_unrefined_balance Extract just the unrefined covariate balance results, if they exist

Description

Extract just the unrefined covariate balance results, if they exist

Usage

```
get_unrefined_balance(pb.object)
```

Arguments

```
pb.object PanelBalance object
```

```
get_unrefined_balance.PanelBalance
```

Extract unrefined covariate balance results, if they exist

Description

Extract unrefined covariate balance results, if they exist

Usage

```
## S3 method for class 'PanelBalance'
get_unrefined_balance(pb.object)
```

Arguments

```
pb.object PanelBalance object
```

Value

A PanelBalance object, with just the unrefined balance results

14 matched_set

matched_set

A constructor for the matched.set class.

Description

Users should never need to use this function by itself. See below for more about matched.set objects.

Usage

```
matched_set(matchedsets, id, t, L, t.var, id.var, treatment.var)
```

Arguments

matchedsets a list of treated units and matched control units. Each element in the list should

be a vector of control unit ids.

id A vector containing the ids of treated units

t A vector containing the times of treatment for treated units.

L integer specifying the length of the lag window used in matching

t.var string specifying the time variable
id.var string specifying the unit id variable

treatment.var string specifying the treatment variable.

The constructor function returns a matched.set object. matched.set objects are a modified list. Each element in the list is a vector of ids corresponding to the control unit ids in a matched set. Additionally, these vectors might have additional attributes — "weights". These correspond to the weights assigned to each control unit, as determined by the specified refinement method. Each element in the list also has a name, which corresponds to the unit id of the treated unit and time of treatment, concatenated together and separated by a period. matched.set objects also have a number of methods defined: summary, plot, and `[`. matched.set objects can be modified manually as long as these conventions (and conventions about other attributes) are maintained. It is important to note that matched.set objects are distinct from PanelMatch objects. matched.set objects are often contained within PanelMatch objects.

PanelData 15

Value

matched.set objects have additional attributes. These reflect the specified parameters when using the PanelMatch function:

lag an integer value indicating the length of treatment history to be used for match-

ing. Treated and control units are matched based on whether or not they have

exactly matching treatment histories in the lag window.

t.var time variable name, represented as a character/string
id.var unit id variable name, represented as a character/string
treatment.var treatment variable name, represented as a character/string

class of the object: should always be "matched.set"

refinement.method

method used to refine and/or weight the control units in each set.

covs.formula One sided formula indicating which variables should be used for matching and

refinement

match.missing Logical variable indicating whether or not units should be matched on the pat-

terns of missingness in their treatment histories

max.match.size Maximum size of the matched sets after refinement. This argument only affects

results when using a matching method

Author(s)

PanelData	Pre-process and balance panel data

Description

Pre-process and balance panel data

Usage

PanelData(panel.data, unit.id, time.id, treatment, outcome)

Arguments

panel.data

A data.frame object containing time series cross sectional data. Time data should be sequential integers that increase by 1. Unit identifiers must be integers. Treatment data must be binary. If time data is non-integer, the package will attempt to sensibly convert it by converting the data to factor, then to integer. If a conversion is performed, a mapping will be returned as an attribute called "time.data.map"

16 PanelEstimate

unit.id	A character string indicating the name of unit identifier in the data. This data must be integer.
time.id	A character string indicating the name of the time variable in the data.
treatment	A character string indicating the name of the treatment variable. The treatment must be a binary indicator variable (integer with 0 for the control group and 1 for the treatment group).
outcome	A character string identifying the outcome variable

Value

PanelData() returns an object of class PanelData. This takes the form of a data.frame object with the following properties and attributes. First, the data has been balanced and sorted. These properties are noted in the "is.balanced" and "is.sorted" attributes, respectively. So, each unit appears the same number of times in the resulting PanelData object, with NAs filling out missing data. Second, the data has been sorted to appear in order for each unit. Next, the PanelData object has the following attributes: "unit.id", "time.id", "treatment", and "outcome" reflecting the variables provided in the specification. If the function attempts to automatically convert time data to be consecutive integers, the mapping between the original time data and the "new" converted time data is provided as a data.frame object and stored as the "time.data.map" attribute.

Examples

PanelEstimate

Estimate a causal quantity of interest

Description

Estimate a causal quantity of interest, including the average treatment effect for treated or control units (att and atc, respectively), the average effect of treatment reversal on reversed units (art), or average treatment effect (ate), as specified in PanelMatch(). This is done by estimating the counterfactual outcomes for each treated unit using matched sets. Users will provide matched sets that were obtained by the PanelMatch function and obtain point estimates and standard errors.

```
PanelEstimate(
   sets,
   panel.data,
   number.iterations = 1000,
   df.adjustment = FALSE,
   confidence.level = 0.95,
```

PanelEstimate 17

```
moderator = NULL,
se.method = "bootstrap",
pooled = FALSE,
include.placebo.test = FALSE,
parallel = FALSE,
num.cores = 1
)
```

Arguments

sets

A PanelMatch object attained via the PanelMatch() function.

panel.data

The same time series cross sectional data set provided to the PanelMatch() function used to produce the matched sets. This should be a PanelData object.

number.iterations

If using bootstrapping for calculating standard errors, this is the number of bootstrap iterations. Provide as integer. If se.method is not equal to "bootstrap", this argument has no effect.

df.adjustment

A logical value indicating whether or not a degree-of-freedom adjustment should be performed for the standard error calculation. The default is FALSE. This parameter is only available for the bootstrap method of standard error calculation.

confidence.level

A numerical value specifying the confidence level and range of interval estimates for statistical inference. The default is .95.

moderator

The name of a moderating variable, provided as a character string. If a moderating variable is provided, the returned object will be a list of PanelEstimate objects. The names of the list will reflect the different values of the moderating variable. More specifically, the moderating variable values will be converted to syntactically proper names using make.names().

se.method

Method used for calculating standard errors, provided as a character string. Users must choose between "bootstrap", "conditional", and "unconditional" methods. Default is "bootstrap". "bootstrap" uses a block bootstrapping procedure to calculate standard errors. The conditional method calculates the variance of the estimator, assuming independence across units but not across time. The unconditional method also calculates the variance of the estimator analytically, but makes no such assumptions about independence across units. When the quantity of interest is "att", "atc", or "art", all methods are available. Only "bootstrap" is available for the ate. If pooled argument is TRUE, then only bootstrap is available.

pooled

Logical. If TRUE, estimates and standard errors are returned for treatment effects pooled across the entire lead window. Only available for se.method = ``bootstrap''

include.placebo.test

Logical. If TRUE, a placebo test is run and returned in the results. The placebo test uses the same specifications for calculating standard errors as the main results. That is, standard errors are calculated according to the user provided se.method and confidence.level arguments (and, if applicable, parallelization specifications).

18 PanelEstimate

parallel Logical. If TRUE and se.method = ``bootstrap'', bootstrap procedure will

be parallelized. Default is FALSE. If se.method is not set to bootstrap, this

option does nothing.

num.cores Integer. Specifies the number of cores to use for parallelization. If se.method =

``bootstrap'' and parallel = TRUE, then this option will take effect. Other-

wise, it will do nothing.

Value

PanelEstimate returns a list of class PanelEstimate containing the following components:

estimates the point estimates of the quantity of interest for the lead periods specified

se.method The method used to calculate standard errors. This is the same as the argument

provided to the function.

bootstrapped.estimates

the bootstrapped point estimate values, when applicable

bootstrap.iterations

the number of iterations used in bootstrapping, when applicable

method refinement method used to create the matched sets from which the estimates

were calculated

lag See PanelMatch() argument lag for more information.

The lead window sequence for which PanelEstimate() is producing point es-

timates and standard errors.

confidence.level

the confidence level

qoi the quantity of interest

matched.sets the refined matched sets used to produce the estimations

standard.error the standard.error(s) of the point estimates

pooled Logical indicating whether or not estimates were calculated for individual lead

periods or pooled.

placebo.test if include.placebo.test = TRUE, a placebo test is conducted using placebo_test()

and returned as a list. See documentation for placebo_test() for more about

each individual item.

PanelMatch 19

Examples

PanelMatch

Create and refine sets of matched treated and control observations

Description

PanelMatch identifies treated observations and a matched set for each treated observation. Specifically, for a given treated unit, the matched set consists of control observations that have an identical treatment history up to a number of lag time periods. A further refinement of the matched set using matching or weighting techniques, described below.

```
PanelMatch(
  panel.data,
  lag,
  refinement.method,
  qoi,
  size.match = 10,
  match.missing = TRUE,
  covs.formula = NULL,
  lead = 0,
  verbose = FALSE,
  exact.match.variables = NULL,
  forbid.treatment.reversal = FALSE,
  matching = TRUE,
  listwise.delete = FALSE,
  use.diagonal.variance.matrix = FALSE,
  restrict.control.period = NULL,
  placebo.test = FALSE
)
```

20 PanelMatch

Arguments

panel.data

A PanelData object containing time series cross sectional data. Time data must be sequential integers that increase by 1. Unit identifiers must be integers. Treatment data must be binary.

lag

An integer value indicating the length of treatment history periods to be matched on

refinement.method

A character string specifying the matching or weighting method to be used for refining the matched sets. The user can choose "mahalanobis", "ps.match", "CBPS.match", "ps.weight", "CBPS.weight", "ps.msm.weight", "CBPS.msm.weight", or "none". The first three methods will use the size.match argument to create sets of at most size.match closest control units. Choosing "none" will assign equal weights to all control units in each matched set. The MSM methods refer to marginal structural models. See Imai, Kim, and Wang (2023) for a more in-depth discussion of MSMs.

qoi

quantity of interest, provided as a string: att (average treatment effect on treated units), atc (average treatment effect of treatment on the control units) art (average effect of treatment reversal for units that experience treatment reversal), or ate (average treatment effect).

size.match

An integer dictating the number of permitted closest control units in a matched set after refinement. This argument only affects results when using a matching method ("mahalanobis" or any of the refinement methods that end in ".match"). This argument is not needed and will have no impact if included when a weighting method is specified (any refinement.method that includes "weight" in the name).

match.missing

Logical variable indicating whether or not units should be matched on the patterns of missingness in their treatment histories. Default is TRUE. When FALSE, neither treated nor control units are allowed to have missing treatment data in the lag window.

covs.formula

One sided formula object indicating which variables should be used for matching and refinement. Argument is not needed if refinement.method is set to "none" If the user wants to include lagged variables, this can be done using a function, "lag()", which takes two, unnamed, positional arguments. The first is the name of the variable which you wish to lag. The second is the lag window, specified as an integer sequence in increasing order. For instance, I(lag(x, 1:4)) will then add new columns to the data for variable "x" for time t-1, t-2, t-3, and t-4 internally and use them for defining/measuring similarity between units. Other transformations using the I() function, such as $I(x^2)$ are also permitted. The variables specified in this formula are used to define the similarity/distances between units.

lead

integer sequence specifying the lead window, for which qoi point estimates (and standard errors) will ultimately be produced. Default is 0 (which corresponds to contemporaneous treatment effect).

verbose

option to include more information about the matched. set object calculations, like the distances used to create the refined sets and weights.

PanelMatch 21

exact.match.variables

character vector giving the names of variables to be exactly matched on. These should be time invariant variables. Exact matching for time varying covariates is not currently supported.

forbid.treatment.reversal

Logical. For the ATT, it indicates whether or not it is permissible for treatment to reverse in the specified lead window. This is defined analogously for the ART. It is not valid for the ATC or ATE. When set to TRUE, only matched sets for treated units where treatment is applied continuously in the lead window are included in the results. Default is FALSE.

matching

logical indicating whether or not any matching on treatment history should be performed. This is primarily used for diagnostic purposes, and most users will never need to set this to FALSE. Default is TRUE.

listwise.delete

TRUE/FALSE indicating whether or not missing data should be handled using listwise deletion or the package's default missing data handling procedures. Default is FALSE. The default procedures function as follows. For every variable to be used in refinement, a new column/variable is added. These are indicator variables which are equal to 1 if the data in the corresponding cell is present and 0 otherwise. If these columns do not contain any variation (e.g. all data is present), then these columns are removed before proceeding with refinement.

use.diagonal.variance.matrix

TRUE/FALSE indicating whether or not a regular covariance matrix should be used in mahalanobis distance calculations during refinement, or if a diagonal matrix with only covariate variances should be used instead. In many cases, setting this to TRUE can lead to better covariate balance, especially when there is high correlation between variables. Default is FALSE. This argument is only necessary when refinement.method = mahalanobis and will have no impact otherwise.

restrict.control.period

(optional) integer specifying the number of pre-treatment periods that treated units and potentially matched control units should be non-NULL and in the control state. For instance, specifying 4 would mean that the treatment history cannot contain any missing data or treatment from t-4 to t.

placebo.test

logical TRUE/FALSE. indicates whether or not you want to be able to run a placebo test. This will add additional requirements on the data – specifically, it requires that no unit included in the matching/refinement process can having missing outcome data over the lag window. Additionally, you should not use the outcome variable in refinement when placebo.test = TRUE.

Value

PanelMatch() returns an object of class PanelMatch. This is a list that contains a few specific elements: First, a matched.set object(s) that has the same name as the provided qoi if the qoi is "att", "art", or "atc". If qoi = "ate" then two matched.set objects will be attached, named "att" and "atc." Please consult the documentation for matched_set() to read more about the structure and usage of matched.set objects. The PanelMatch object also has some additional attributes that track metadata about the specification, like the names of the unit and time identifier variables.

```
dem.sub <- dem[dem[, "wbcode2"] <= 100, ]</pre>
dem.sub.panel <- PanelData(dem.sub, "wbcode2", "year", "dem", "y")</pre>
# create subset of data for simplicity
PM.results <- PanelMatch(panel.data = dem.sub.panel, lag = 4,
                         refinement.method = "ps.match",
                         match.missing = TRUE,
                         covs.formula = ~ tradewb,
                         size.match = 5, qoi = "att",
                         lead = 0:4,
                          forbid.treatment.reversal = FALSE)
# include lagged variables
PM.results <- PanelMatch(panel.data = dem.sub.panel, lag = 4,
                         refinement.method = "ps.weight",
                         match.missing = TRUE,
                        covs.formula = ~ tradewb + I(lag(tradewb, 1:4)) + I(lag(y, 1:4)),
                         size.match = 5, qoi = "att",
                         lead = 0:4,
                         forbid.treatment.reversal = FALSE)
```

placebo_test

Conduct a placebo test

Description

Calculate the results of a placebo test, looking at the change in outcome at time = t-1, compared to other pre-treatment periods in the lag window.

```
placebo_test(
  pm.obj,
  panel.data,
  lag.in = NULL,
  number.iterations = 1000,
  confidence.level = 0.95,
  plot = FALSE,
  se.method = "bootstrap",
```

placebo_test 23

```
parallel = FALSE,
num.cores = 1,
...
)
```

Arguments

pm.obj an object of class PanelMatch

panel.data PanelData object

lag.in integer indicat

integer indicating earliest the time period(s) in the future for which the placebo test change in outcome will be calculated. Calculations will be made over the period t - max(lag) to t-2, where t is the time of treatment. The results are similar to those returned by PanelEstimate(), except t-1 is used as the period of comparison, rather than the lead window. If not specified, the placebo test is conducted for periods from t - max(lag) to t-2.

number.iterations

integer specifying the number of bootstrap iterations. This argument only has an effect if standard errors are calculated with the bootstrap.

confidence.level

confidence level for the calculated standard error intervals. Should be specified

as a numeric between 0 and 1.

plot logical indicating whether or not a plot should be generated, or just return the

raw data from the calculations

se.method character string describing the type of standard error to be used. Valid in-

puts include "bootstrap", "conditional" and "unconditional". When the QOI is ATE, only bootstrap can be used. See the documentation of this argument in

PanelEstimate() for more.

parallel Logical. If TRUE and se.method = "bootstrap", bootstrap procedure will be

parallelized. Default is FALSE. If se.method is not set to bootstrap, this

option does nothing."

num.cores Integer. Specifies the number of cores to use for parallelization. If se.method

= "bootstrap" and parallel = TRUE, then this option will take effect. Other-

wise, it will do nothing.

... extra arguments to be passed to plot()

Value

list with 2 or 3 elements: "estimate", which contains the point estimates for the test, "standard.errors" which has the standard errors for each period and optionally "bootstrapped.estimates", containing the bootstrapped point estimates for the test for each specified lag window period.

```
dem.sub <- dem[dem[, "wbcode2"] <= 100, ]
dem.sub.panel <- PanelData(dem.sub, "wbcode2", "year", "dem", "y")
# create subset of data for simplicity
PM.results <- PanelMatch(panel.data = dem.sub.panel, lag = 4,</pre>
```

24 plot.matched.set

plot.matched.set

Plot the distribution of control unit weights

Description

The method creates a heatmap with the following characteristics. The heatmap grid is m x n, where m is the number of treated observations (as identified by i,t pairs) and n is the number of units. Treated observations represent the rows, and every unit in the data set form the columns. The figure then shows the calculated weights or distances (as specified) for each control unit within the matched set as identified by the row. Weights/distances that are missing or zero are not considered in the shading scheme and are both treated as NA for all practical purposes. Note that not all refinement methods will return a distance. Those that do also require verbose = TRUE in the PanelMatch specification. For example say (2, 5) is a treated observation and units 1, 4, 8 are matched as controls. Row i will represent (2,5) in the matrix, M. The columns indexed by w, x, and y, correspond to units 1, 4, and 8. M[i, w], M[i, x], M[i, y] then contain the weights or pairwise distances of units 1, 4, and 8 within that matched set.

Usage

```
## $3 method for class 'matched.set'
plot(
    x,
    ...,
    panel.data,
    type = "weights",
    include.missing = TRUE,
    low.color = "blue",
    mid.color = "white",
    high.color = "red",
    missing.color = "grey50"
)
```

Arguments

```
x a matched.set object... Not usedpanel.data a PanelData object
```

plot.PanelBalance 25

type	character indicating whether or not weights or distances should be plotted
include.missing	
	logical. When TRUE, all units appear as columns, including those that are never included in any matched sets. When FALSE, only units that appear in at least one matched set are included.
low.color	option passed to ggplot2::scale_fill_gradientn(). The color representing the low weight/distance values.
mid.color	option passed to $ggplot2::scale_fill_gradientn()$. The color representing the medium weight/distance values.
high.color	option passed to ggplot2::scale_fill_gradientn(). The color representing the high weight/distance values.
missing.color	option passed to ggplot2::scale_fill_gradientn(). The color representing the missing/zero weight/distance values.

Value

returns a ggplot2::geom_tile() object producing a plot in alignment with the description above

Examples

 $\verb"plot.PanelBalance"$

Plot covariate balance results Create figures displaying covariate balance results for one or more PanelMatch configurations. Users can customize these visualizations.

Description

Plot covariate balance results Create figures displaying covariate balance results for one or more PanelMatch configurations. Users can customize these visualizations.

26 plot.PanelBalance

Usage

```
## S3 method for class 'PanelBalance'
plot(
  Х,
  type = "panel",
  reference.line = TRUE,
  legend = TRUE,
 ylab = NULL,
  include.treatment.period = TRUE,
  include.unrefined.panel = TRUE,
  legend.position = "topleft",
 main = NULL,
 main.unrefined = NULL
)
```

Arguments

PanelBalance object Х

additional parameters to be passed to base::plot()

type

character specifying which type of plot to produce. Can be either "panel" or "scatter". When "panel," covariate balance results for covariates are shown over the lag period. When "scatter," the figure has the following characteristics. Each point on the plot represents a specific covariate at a particular time period in the lag window from t-L to t-1. The horizontal axis represents the covariate balance for this particular variable and time period before refinement is applied, while the vertical axis represents the post-refinement balance value.

reference.line logical. Include a reference line at y = 0? Only applicable to the panel plot.

logical. Describes whether or not to include a legend. legend

ylab character. Y-axis label.

include.treatment.period

Logical. Describes whether or not the treatment period should be included on the panel plot. Default is TRUE.

include.unrefined.panel

logical indicating whether or not unrefined balance plots should be returned for panel plot. Only applicable to panel plot. Default is TRUE.

legend.position

character. Describes where the legend should be placed on the figure. Uses base R syntax.

main

character. Either a single title to be used for all plots or a character vector providing a name for each figure, which should be the same length as the number of 'PanelMatch' configurations in the 'PanelBalance' object. By default, main is set to NULL and figures are titled the same as the 'PanelMatch' objects the figures are based on.

main.unrefined character. This argument is the same as main, but applies to the set of figures corresponding to the unrefined covariate balance results. This is only used when applicable – otherwise it has no effect.

plot.PanelData 27

Value

returns a set of base R plots, depending on the specification of "panel" or "scatter" above. When type = "panel" and include.unrefined.panel = TRUE, two sets of plots are returned. The first set shows covariate balance levels for the specified PanelMatch configurations. The second set shows covariate balance levels for the same PanelMatch configurations, but with all control units receiving equal weight (i.e., balance levels prior to refinement). If include.unrefined.panel = FALSE, only the first set of figures are returned. The sets of figures are both returned in the same order as the PanelMatch configurations specified to get_covariate_balance() that compose the PanelBalance object. When type = "scatter", the visualization described above is produced, with all configurations shown on the same plot with different symbols.

Examples

```
dem$rdata <- runif(runif(nrow(dem)))</pre>
dem.panel <- PanelData(dem, "wbcode2", "year", "dem", "y")</pre>
pm.obj <- PanelMatch(lead = 0:3, lag = 4, refinement.method = "mahalanobis",
                     panel.data = dem.panel, match.missing = TRUE,
                 covs.formula = ~ tradewb + rdata + I(lag(tradewb, 1:4)) + I(lag(y, 1:4)),
                      size.match = 5, qoi = "att")
# create multiple configurations to compare
pm2 <- PanelMatch(lead = 0:3, lag = 4, refinement.method = "ps.match",</pre>
                  panel.data = dem.panel, match.missing = TRUE,
                covs.formula = ~ tradewb + rdata + I(lag(tradewb, 1:4)) + I(lag(y, 1:4)),
                  size.match = 5, qoi = "att")
pb <- get_covariate_balance(pm.obj, pm2,</pre>
                             include.unrefined = TRUE,
                             panel.data = dem.panel,
                             covariates = c("tradewb", "rdata"))
plot(pb, type = "panel", include.unrefined.panel = TRUE)
plot(pb, type = "scatter")
# only show refined balance figures
plot(pb, type = "panel", include.unrefined.panel = FALSE)
```

plot.PanelData

Create basic plots of PanelData objects

Description

Create basic plots of PanelData objects

```
## S3 method for class 'PanelData'
plot(x, ..., plotting.variable = NA)
```

28 plot.PanelEstimate

Arguments

```
x PanelData object
... Not used
plotting.variable
```

character string specifying which variable to plot in the resulting figure. The values of this variable will be used to fill in cells on the resulting heatmap. Defaults to whatever is specified as the treatment variable.

Value

Returns a ggplot2 object created by geom_tile(). The basic figure shows units along the y-axis and time along the x-axis. The figure takes the form of a heatmap. The value of the plotting.variable argument is used to fill in the color of the cells.

Examples

```
dem$rdata <- rnorm(nrow(dem))
d <- PanelData(dem, "wbcode2", "year", "dem", "y")
plot(d)
plot(d, plotting.variable = "rdata")</pre>
```

plot.PanelEstimate

Plot point estimates and standard errors from a PanelEstimate calculation.

Description

The plot.PanelEstimate method takes an object returned by the PanelEstimate function and plots the calculated point estimates and standard errors over the specified lead time period. The only mandatory argument is an object of the PanelEstimate class.

```
## S3 method for class 'PanelEstimate'
plot(
    X,
    ylab = "Estimated Effect of Treatment",
    xlab = "Time",
    main = "Estimated Effects of Treatment Over Time",
    ylim = NULL,
    pch = NULL,
    cex = NULL,
    confidence.level = NULL,
    bias.corrected = FALSE,
    ...
)
```

plot.PanelMatch 29

Arguments

	X	a PanelEstimate object
	ylab	default is "Estimated Effect of Treatment." This is the same argument as the standard argument for $plot()$
	xlab	default is "Time". This is the same argument as the standard argument for $plot()$
	main	default is "Estimated Effects of Treatment Over Time". This is the same argument as the standard argument for plot
	ylim	default is NULL. This is the same argument as the standard argument for $plot()$
	pch	default is NULL. This is the same argument as the standard argument for $plot()$
	cex	default is NULL. This is the same argument as the standard argument for $plot()$
confidence.level		
		confidence.level Confidence level to be used for confidence interval calculations. Must be numeric between 0 and 1. If NULL, confidence level from $PanelEstimate()$ specification is used.
	bias.corrected	logical indicating whether or not bias corrected estimates should be plotted Default is FALSE. This argument only applies for standard errors calculated with the bootstrap.
		Additional optional arguments to be passed to plot().

30 plot.PanelMatch

Description

A plot method for creating a histogram of the distribution of the sizes of matched sets. This method accepts all standard optional hist arguments via the \dots argument. By default, empty matched sets (treated units that could not be matched with any control units) are noted as a vertical bar at x = 0 and not included in the regular histogram. See the include.empty.sets argument for more information about this. If the quantity of interest is ATE, a plot will be returned for the matched sets associated with the att and the atc.

Usage

```
## S3 method for class 'PanelMatch'
plot(
    x,
    ...,
    border = NA,
    col = "grey",
    ylab = "Frequency of Size",
    xlab = "Matched Set Size",
    lwd = NULL,
    main = "Distribution of Matched Set Sizes",
    freq = TRUE,
    include.empty.sets = FALSE
)
```

Arguments

X	a PanelMatch object
	optional arguments to be passed to hist()
border	default is NA. This is the same argument as the standard argument for hist()
col	default is "grey". This is the same argument as the standard argument for hist()
ylab	default is "Frequency of Size". This is the same argument as the standard argument for hist()
xlab	default is "Matched Set Size". This is the same argument as the standard argument for hist()
lwd	default is NULL. This is the same argument as the standard argument for hist()
main	default is "Distribution of Matched Set Sizes". This is the same argument as the standard argument for hist
freq	default is TRUE. See freq argument in hist() function for more.
include.emptv.sets	

logical value indicating whether or not empty sets should be included in the histogram. default is FALSE. If FALSE, then empty sets will be noted as a separate vertical bar at x=0. If TRUE, empty sets will be included as normal sets.

print.matched.set 31

Examples

print.matched.set

Print matched.set objects.

Description

Print matched.set objects.

Usage

```
## S3 method for class 'matched.set'
print(x, ..., verbose = FALSE, n = 5, show.all = FALSE)
```

Arguments

x a matched.set object
 ... Not used. additional arguments to be passed to print
 verbose logical indicating whether or not output should be printed in expanded/raw list form. The verbose form is not recommended unless the data set is small. Default is FALSE, which prints an overview of matched set sizes.
 n Integer. Integer. Number of matched sets to display information about as a preview. Default is 5.
 show.all Logical. By default ('show.all = FALSE'), the print method only shows a small preview of the sizes of matched sets. When set to TRUE, a full summary description of matched set sizes is shown.

Value

Returns nothing, but prints information about matched sets: treated observation IDs, the time of treatment, and the size of matched sets.

32 print.PanelBalance

Examples

print.PanelBalance

Print basic information about PanelBalance objects

Description

This function prints out covariate balance information for all of the PanelMatch configurations specified within a PanelBalance object. Specifically it prints out the name of the PanelMatch object(s), and covariate balance measures over the specified time period after refinement. If no refinement was applied, then these unrefined results will be shown.

Usage

```
## S3 method for class 'PanelBalance'
print(x, ...)
```

Arguments

x PanelBalance object

... Not used

Value

Nothing

print.PanelData 33

print.PanelData

Print PanelData objects and basic metadata

Description

Print PanelData objects and basic metadata

Usage

```
## S3 method for class 'PanelData'
print(x, ..., n = 5, verbose = FALSE)
```

Arguments

x	PanelData object
	additional arguments to be passed to print.data.frame()
n	Integer. Number of rows to print by default for previewing data. Default is 5.
verbose	Logical. Print the entire data frame, rather than just a preview. Default is FALSE.

Value

Returns nothing but prints PanelData object. This is a data frame that has been balanced, sorted, and tagged with important metadata to facilitate the use of other functions.

```
d <- PanelData(dem, "wbcode2", "year", "dem", "y")
print(d)</pre>
```

34 print.PanelMatch

print.PanelEstimate

Print point estimates and standard errors

Description

Print point estimates and standard errors

Usage

```
## S3 method for class 'PanelEstimate'
print(x, ...)
```

Arguments

x PanelEstimate object

... Not used

Examples

print.PanelMatch

Print PanelMatch objects.

Description

Print PanelMatch objects.

```
## S3 method for class 'PanelMatch'
print(x, ..., verbose = FALSE, n = 5, show.all = FALSE)
```

summary.matched.set 35

Arguments

X	a PanelMatch object
	additional arguments to be passed to print.matched.set
verbose	logical indicating whether or not underlying data should be printed in expanded/raw list form. The verbose form is not recommended unless the data set is small. Default is FALSE
n	Integer. Number of matched sets to display information about as a preview. Default is 5.
show.all	Logical. By default ('show.all = FALSE'), the print method only shows a small preview of the sizes of matched sets. When set to TRUE, a full summary description of matched set sizes is shown.

Examples

summary.matched.set

Summarize information about a matched.set object and the matched sets contained within them.

Description

A method for viewing summary data about the sizes of matched sets and metadata about how they were created. This method accepts all standard summary arguments.

Usage

```
## S3 method for class 'matched.set'
summary(object, ..., verbose = TRUE)
```

Arguments

object a matched. set object

... Optional additional arguments to be passed to the summary function

verbose Logical value specifying whether or not a longer, more verbose summary should

be calculated and returned. Default is TRUE.

Value

list object with either 5 or 1 element(s), depending on whether or not verbose is set to TRUE or not.

overview

A data.frame object containing information about the treated units (unit id, time of treatment), and the number of matched control units with weights zero and above.

set.size.summary

a summary object summarizing the minimum, maximum, and IQR of matched set sizes

number.of.treated.units

The number of unit, time pairs that are considered to be "treated" units

num.units.empty.set

The number of units treated at a particular time that were not able to be matched to any control units

lag

The size of the lag window used for matching on treatment history. This affects which treated and control units are matched.

Examples

summary.PanelBalance Summarize covariate balance over time

Description

Summarize covariate balance over time

```
## $3 method for class 'PanelBalance'
summary(
  object,
  qoi = NULL,
  include.unrefined = TRUE,
```

summary.PanelBalance 37

```
unrefined.only = FALSE,
include.treatment.period = TRUE,
...
)
```

Arguments

object PanelBalance object

qoi Character. Valid values include "att", "art", or "atc". Specifying which QOI

information to extract and summarize.

include.unrefined

logical. Indicates whether or not unrefined balance results should be included in

the summary.

unrefined.only logical. Indicates whether or not only unrefined balance results should be in-

cluded in the summary.

include.treatment.period

logical. Indicates whether or not the treatment period should be included in the summary. Default is TRUE. This is recommended to be set to TRUE unless there are strong substantive reasons to do otherwise.

... Not used

Value

returns a list of matrices with covariate balance results calculated. Each element in the list corresponds to a PanelMatch configuration given to get_covariate_balance() and are returned in order. These elements should also have names that correspond to the names of the PanelMatch variables provided to the function. Note that if a configuration has qoi = "ate", the corresponding element in the returned list will also be a list, containing balance results corresponding to the ATT and ATC. Otherwise, each element in the returned list will be a matrix. Each matrix entry corresponds to balance results for a particular covariate in a particular period. When unrefined balance results are included, users will see additional columns with "_unrefined" appended to covariate names. These correspond to the unrefined balance results for a particular covariate-period. If 'unrefined.only = TRUE', then the names of the elements will have "_unrefined" appended to them.

summary.PanelData

Summarize information about variable names, and unit, time, and treatment data in a PanelData object

Description

Summarize information about variable names, and unit, time, and treatment data in a PanelData object

Usage

```
## S3 method for class 'PanelData'
summary(object, ...)
```

Arguments

object PanelData object

Not used

Value

Returns a data.frame object, with columns "quantity" and "value." Within the data frame the following information is returned: The name of the unit id variable, the name of the time id variable, the name of the treatment variable, the name of the outcome variable, the number of unique units found in the data, the number of unique time periods found in the data and the percentage of treated periods that are missing treatment data.

Examples

```
d <- PanelData(dem, "wbcode2", "year", "dem", "y")
summary(d)</pre>
```

summary.PanelEstimate Get summaries of PanelEstimate objects and calculations

Description

summary.PanelEstimate takes an object returned by PanelEstimate, and returns a summary table of point estimates and confidence intervals

summary.PanelEstimate

Usage

```
## S3 method for class 'PanelEstimate'
summary(
   object,
   confidence.level = NULL,
   verbose = FALSE,
   bias.corrected = FALSE,
   ...
)
```

Arguments

 $object \hspace{1cm} A \hspace{0.1cm} \textit{PanelEstimate object}$

confidence.level

Confidence level to be used for confidence interval calculations. Must be numeric between 0 and 1. If NULL, confidence level from PanelEstimate()

39

specification is used.

verbose logical indicating whether or not output should be printed in an expanded form.

Default is FALSE

bias.corrected logical indicating whether or not bias corrected estimates should be provided.

Default is FALSE. This argument only applies for standard errors calculated

with the bootstrap.

. . . optional additional arguments. Currently, no additional arguments are supported.

40 summary.PanelMatch

summary.PanelMatch

Summarize information about a PanelMatch object and the matched sets contained within them.

Description

A method for viewing summary data about the sizes of matched sets, the number of treated units, and the number of empty matched sets. If the quantity of interest is ate, then a summary will be provided for the matched sets associated with the att and the atc.

Usage

```
## S3 method for class 'PanelMatch'
summary(object, ...)
```

Arguments

object a PanelMatch object
... Not used

Value

A list of data frame(s) containing information about matched sets associated with the specified qoi. If the qoi is "att", "art", or "atc", then the returned list contains one data frame and the element is named for the specified qoi. If the qoi is "ate", then a list of two elements is returned, with one data frame corresponding to the "att" and the other to the "atc". The data frame contains summary information about the sizes of matched sets, along with information about the number of treated observations and the number of empty sets. Specifically, it contains the minimum, 1st quartile, median, mean, 3rd quartile, and maximum matched set size. It also contains the number of treated units total and the number of empty matched sets.

weights 41

weights

Get weights of matched control units See weights.matched.set method

Description

Get weights of matched control units See weights.matched.set method

Usage

```
weights(object)
```

Arguments

object

Matched.set object

weights.matched.set

Extract the weights of matched control units

Description

Extract the weights of matched control units

Usage

```
## S3 method for class 'matched.set'
weights(object)
```

Arguments

object

matched.set object, extracted using the get.PanelMatch() method

Value

list of named vectors. Each list element corresponds to a particular treated observation and contains the matched control units, along with their weights. These correspond to the "weights" attribute, which are calculated in the PanelMatch refinement process.

42 [.PanelBalance

[.matched.set

Subset matched.set object

Description

Subsets matched.set objects while preserving attributes.

Usage

```
## S3 method for class 'matched.set'
x[i, j = NULL, drop = NULL]
```

Arguments

x matched.set object

i numeric. specifies the index of which element to extract.

j NULL drop NULL

[.PanelBalance

Subset PanelBalance objects

Description

Subset PanelBalance objects

Usage

```
## S3 method for class 'PanelBalance' x[i, \ldots]
```

Arguments

x PanelBalance object

i numeric. Specifies which element to extract. Substantively, it specifies which

PanelMatch configuration data to extract.

... Not used

Value

Returns balance information for specified PanelMatch configuration. Note that results are still returned as a PanelBalance object. In order to return a list, use the [[operator

[.PanelBalance 43

```
dem$rdata <- runif(runif(nrow(dem)))</pre>
